## 1 Normals and curvature

There is a deep link between the evolution of the normal along a curve and the curvature.

Let  $C$  be a planar curve. To define the curvature at a point, we can consider the case of a straight line. We can admit that in this case the curvature is zero along the line. For a portion of a circle, the curvature is defined to be inversely proportional to the radius of the circle:

$$\kappa = \frac{1}{R} \quad (1)$$

More precisely, for any curve, we can locally approximate a sufficiently regular curve ( $\mathcal{C}^2$  is enough) at a point by a circle that best approximates it locally (see Fig. 1. This circle is tangent to  $C$  and is called an *osculating circle*. The radius of this circle defines the curvature.

Another way to define the curvature is to consider a point moving at a constant speed along the curve  $C$ . The variation of the tangent vector along the curve defines the curvature. This is equivalent to specifying the acceleration of the point.

$$\kappa = \frac{d\mathbf{T}}{ds}, \quad (2)$$

where  $s$  is a parametrisation of the curve. Both definition of the curvature are in fact equivalent (see Fig. 2).

Figure 1: The notion of an osculating circle (best local approximation) defines the curvature as the inverse of the radius of the circle.

Figure 2: We can write  $\sin d\theta \approx d\theta = \frac{ds}{R}$ . As  $ds$  tends to zero, we have  $R = \frac{d\theta}{ds} = \frac{d\mathbf{T}}{ds}$ .

## Parametrisation

Let  $\gamma(t)$  be a parametrisation of the curve  $C$ , i.e.

$$\gamma(t) = (x(t), y(t)) \quad (3)$$

This defines the position of a point on the curve over time. We assume an injective parametrisation, i.e. such that the speed  $\gamma'(t)$  is never zero. This means

$$\forall t, \|\gamma'(t)\|^2 = x'(t)^2 + y'(t)^2 > 0 \quad (4)$$

In this case, we can re-parametrise the curve with curvilinear abscissa  $s$  in such a way that the speed is constant and equal to one.

$$\forall s, \gamma'(s)^2 = x'(s)^2 + y'(s)^2 = 1 \quad (5)$$

In this parametrisation,  $\gamma'$  is the unit tangent velocity vector  $\mathbf{T}$ . If  $\mathbf{N}$  is the unit normal vector to the curve, we have

$$\mathbf{T}'(s) = \kappa(s)\mathbf{N}(s) \quad (6)$$

We note that instead of deriving the unit tangent vector, we can also consider deriving the unit normal vector. This is because  $\mathbf{N}$  is  $\mathbf{T}$  rotated by  $\frac{\pi}{2}$ , i.e.  $\mathbf{N}(x, y) = (-y'(s), x'(s))$ . This yields

$$\mathbf{N}'(s) = \kappa(s)\mathbf{T}(s) \quad (7)$$

We will make use of that fact in the next section.

## Level sets

In imaging it can be difficult to represent a parametric curve because of discretization effects. It is common to represent it by a *level set* (see Fig. 3).

Let  $\phi(x, y)$  be a  $\mathcal{C}^2$  function in a domain  $\Omega$ . We define the curve  $\Gamma$  as the zero-level-set of this function

$$\Gamma = \{(x, y), \phi(x, y) = 0\} \quad (8)$$

$\Gamma$  is a set and no longer a parametrized curve, however we can manipulate it by working on the underlying  $\phi$  function. This is the main idea behind the level-set method [1].

Figure 3: Representing a curve by a level set.

Figure 4: The faster the normal evolves along a curve, the higher the curvature.

## Level sets and curvature

Curvature is easy to define in the level set case. For any point  $(x, y)$  in  $\Omega$ ,  $\nabla\phi(x, y)$  is the gradient at  $(x, y)$ . If we consider the level-set at  $(x, y, \phi(x, y))$ , i.e. the curve that passes through  $(x, y)$  at level  $\phi(x, y)$ , then  $\nabla\phi(x, y)$  is the normal vector to this curve at  $(x, y)$ . The unit normal is given by

$$\mathbf{n}(x, y) = \frac{\nabla\phi}{|\nabla\phi|}(x, y) \quad (9)$$

The curvature is given by the derivative of this expression. However this is a multidimensional derivative. Since  $\nabla\phi$  is a vector, we must use the divergence operator:

$$\kappa = \nabla \cdot \frac{\nabla\phi}{|\nabla\phi|} \quad (10)$$

This is in particular true for the computation of the curvature of  $\Gamma$ .

## 2 Application to our problem

We want to calculate  $n$ , the number of tests along the segment necessary to compute with a reasonable tolerance to verify the segment doesn't cross a concavity of the perfusion territory:

$$n \propto \frac{|p_1 - p_0|}{R} \quad (11)$$

$R$  is an approximation of the local curvature along the segment by estimating the divergence at each point  $p_1$  and  $p_2$ , called  $R_1$  and  $R_2$  respectively :

$$R = \max(|R_1|, |R_2|) \quad (12)$$

The figure 5 illustrates the relationship between  $D = |p_1 - p_0|$ ,  $R_1$ ,  $R_2$  and  $n$ .

Figure 5: When  $D$  gets bigger relatively to  $\max(|R_1|, |R_2|)$ , the value of  $n$  is also higher to detect if the segment crosses the perfusion territory.

The divergence of a continuously differentiable vector field  $\omega$  is equal to the scalar value function:

$$\text{div}(\omega) = \left( \frac{\partial}{\partial x}, \frac{\partial}{\partial y} \right) \cdot (\omega_x, \omega_y) \quad (13)$$

$$\text{div}(\omega) = (\omega_x(x, y) - \omega_x(x - 1, y)) + (\omega_y(x, y) - \omega_y(x, y - 1)) \quad (14)$$

with

$$\omega_x = \nabla_x \omega = \omega(x + 1, y) - \omega(x, y) \quad (15)$$

and

$$\omega_y = \nabla_y \omega = \omega(x, y + 1) - \omega(x, y) \quad (16)$$
